

Wind Power Basics

RENEWABLE ENERGY
THE INFINITE POWER
OF TEXAS

HIGHLIGHTS

- Wind power is one of the oldest renewable technologies
- As wind speed doubles, power generation capability increases eightfold
- Higher is better: hilltops and tall towers lead to greater energy production

INTRODUCTION

What creates wind? Wind is created from differences between higher pressure and lower pressure caused by unequal heating and cooling of the Earth and atmosphere. Air always tries to flow from higher to lower pressure until the pressures are equalized.

The greater the difference in pressure between two points, the faster the wind speed will be. Other things such as mountains and valleys can affect the wind as well.

Humans have been harnessing the wind ever since farmers in ancient Persia figured out how to use wind power to pump water. Wind power turns the kinetic energy of the wind into mechanical or electrical power that can be used for a variety of tasks. Whether the

MECHANICAL PUMP WINDMILL These simple wind-driven machines, which utilize a long sucker rod to pump underground water to the surface, were a critical tool in settling the West.

task is creating electricity or pumping water, the wind offers an inexpensive, clean and reliable form of power. Wind farms are now part of the Texas landscape with over 3,500 megawatts (MW) installed as of late 2007.

WIND ON THE WATER

Whether powering sailboats across the surface of the water or pumping water from one location to another, the wind is a good source of power. Wind provided early explorers with the engine they needed to cross oceans and discover new lands. On land, the oldest and most widespread use of wind power is for pumping water. In virtually every country on Earth, humans are using wind power to either pump water from the ground or move it from one location to another. Here in Texas, where more than 80,000 windmills are in use, rural residents have long relied on windmills to provide water for livestock and human use.

THE HOWS AND WHYS OF WIND POWER

Wind is moving air. The engine that drives this movement is the sun. A good illustration is the sea breeze that blows along the Texas Gulf coast. As the coastal land soaks up sunshine, the air above it heats up and rises. Air over the cooler ocean water then rushes inland. The result is a very dependable wind source suitable for making anything from electricity to windsurfing.

Although modern wind turbines can produce some electricity in light winds, the stronger the breeze the better. The power available in the wind is proportional to the cube of its speed. That means that if the wind speed doubles, say from 10 to 20 miles per hour, the power available to a wind generator increases by a factor of eight, for instance from 1,000 Watts to 8,000 Watts.

One easy way to access higher wind speeds is simply to go higher above ground level.

WIND POWER DEPENDS ON ELEVATION AND WIND SPEED *Wind Class is a relative scale used to characterize wind potential of any location. Wind Class of 3 or above are generally regarded as being suitable for commercial wind farm development.*

Winds high above the ground are stronger than winds near the ground. On average a five-fold increase in elevation, say raising the height of the wind machine from 10 feet to 50 feet, will result in twice as much available wind power. That's why wind turbines are perched on tall towers and are often located on mountains or hilltops.

Given the need for strong winds, finding the best sites for commercial wind farms is critical. The location of power plants fueled by wind should be near existing power lines and in the windiest sites available. To compete head-to-head with fossil fuel generating technologies, wind turbines are best located in areas where wind speeds are 16-20 mph at 50 m height. In Texas, the best locales are found in far west Texas and the Texas Panhandle.

Air temperature is also an important factor in wind power generation. Cold air is denser than hot air. Thus, wind turbines are able to generate about 5% more power at any given

wind speed in the winter than they are during the hot days of summer.

MAKING WATTS FROM WIND

The blades on a wind turbine are similar to the propeller blades on an airplane. The rotor blades generate lift from the passing wind, causing them to rotate the hub of the turbine. The rotating action of the hub then turns a generator, which creates electricity. A gearbox is generally necessary to optimize the power output from the machine. That power is then either fed into the electric grid or stored in batteries for use on-site.

While wind speed is important, so is the size of the rotor. On a turbine, the power available to the blades is proportional to the square of the diameter of the rotor. In other words, simply by making the turbine blades

twice as long and beefing up the generator, you increase the power producing capability of the turbine by a factor of four.

Modern wind turbines come in two varieties: horizontal axis and vertical axis. Horizontal axis turbines have blades that spin on an axis that is parallel to the ground. These systems often look like the propeller on an airplane. Vertical axis systems have blades that spin

on a vertical axis giving them an appearance somewhat like giant eggbeaters.

Although large utilities are getting the most attention for their move into wind power, rural residents in all 50 states and dozens of foreign countries have quietly been installing small-scale wind generation systems. These systems can be obtained for as little as \$1,000 and are perfect compliments to solar photovoltaic systems. Several vendors sell ready-made towers and turbines that are easily installed.

ELECTRICITY GENERATING WIND TURBINE The major components of this device are the blades, shaft, gearbox and generator. On large machines, additional controllers and drive motors ensure that the machine is positioned for optimal capture of the wind.
